# Chapter 11: File System Implementation

- File structure
  - Logical storage unit
  - Collection of related information
- File system resides on secondary storage (such as disks)
- 1. Boot control block information needed to boot
- Volume control block information about volume/partitions (# blocks, size of blocks, free block count, free block pointers)
- 3. Directory structure (inode)
- 4. Per file control blocks
  - File system organized into layers

## Layered File System

## A Typical File Control Block

File control block – storage structure consisting of information about a file

file permissions

file dates (create, access, write)

file owner, group, ACL

file size

file data blocks or pointers to file data blocks

## In-Memory File System Structures

## Virtual File Systems

- There are many different file systems available on any operating systems
  - Windows: NTFS, FAT, FAT32
  - Linux: ext2/ext3, ufs, vfat, ramfs, tmpfs, reiserfs, xfs ...
- Virtual File Systems (VFS) provide an objectoriented way of implementing file systems
- VFS allows the same system call interface (the API) to be used for different types of file systems
- The API is to the VFS interface, rather than any specific type of file system

## Schematic View of Virtual File System

## **Directory Implementation**

- Directories hold information about files
- Linear list of file names with pointer to the data blocks.
  - simple to program
  - time-consuming to execute

#### ► Hash Table – linear list with hash data structure.

- decreases directory search time
- collisions situations where two file names hash to the same location
- fixed size

## **Allocation Methods**

- An allocation method refers to how disk blocks are allocated for files:
- Contiguous allocation
- Linked allocation
- Indexed allocation

## **Contiguous Allocation**

- Each file occupies a set of contiguous blocks on the disk
- Simple only starting location (block #) and length (number of blocks) are required
- Random access
- Wasteful of space (dynamic storageallocation problem)
- Files cannot grow

## **Contiguous Allocation of Disk Space**

## **Extent-Based Systems**

- Many newer file systems (I.e. Veritas File System) use a modified contiguous allocation scheme
- Extent-based file systems allocate disk blocks in extents
- An **extent** is a contiguous block of disks
  - Extents are allocated for file allocation
  - A file consists of one or more extents.

Each file is a linked list of disk blocks: blocks may be scattered anywhere on the disk.

- Simple need only starting address
- Free-space management system no waste of space
- No random access

#### Linked Allocation

#

## File-Allocation Table (DOS FAT)

## **Indexed Allocation**

- Brings all pointers together into the index block.
- Logical view.

index table

#### **Example of Indexed Allocation**

## Indexed Allocation (Cont.)

- Need index table
- Random access
- Dynamic access without external fragmentation, but have overhead of index block.
- Mapping from logical to physical in a file of maximum size of 256K words and block size of 512 words. We need only 1 block for index table.

## Indexed Allocation – Mapping (Cont.)

#### Combined Scheme: UNIX (4K bytes per block)
