Quantization

$$\hat{F}(u,v) = round\left(\frac{F(u,v)}{Q(u,v)}\right)$$

F(u, v) represents a DCT coefficient, Q(u, v) is a "quantization matrix" entry, and *F̂*(*u*,*v*) represents the quantized DCT coefficients which JPEG will use in the succeeding entropy coding

quantization step is the main source for loss in JPEG

- The entries of Q(u, v) tend to have larger values towards the lower right corner. This aims to introduce more loss at the higher spatial frequencies — a practice supported by Observations 1 and 2
- default Q(u, v) values obtained from psychophysical studies with the goal of maximizing the compression ratio while minimizing perceptual losses in JPEG images.

Run-length Coding on AC coefficients

To make it most likely to hit a long run of zeros: a zig-zag scan is used to turn the 8×8 matrix f(u,v) into a 64-vector

2/2/09

DPCM on DC coefficients

- The DC coefficients are coded separately from the AC ones. Differential Pulse Code modulation (DPCM) is the coding method
- If the DC coefficients for the first 5 image blocks are 150, 155, 149, 152, 144, then the DPCM would produce 150, 5, -6, 3, -8, assuming d_i = DC_{i+1} -DC_i, and d₀ = DC₀
- AC components are Huffman coded

Four Commonly Used JPEG Modes

- Sequential Mode the default JPEG mode, each graylevel image or color image component is encoded in a single left-to-right, top-to-bottom scan
- Progressive Mode
- Hierarchical Mode
- Lossless Mode discussed in Chapter 7

Progressive Mode

Progressive JPEG delivers low quality versions of the image quickly, followed by higher quality passes

- Spectral selection: Takes advantage of the "spectral" (spatial frequency spectrum) characteristics of the DCT coefficients: higher AC components provide detail information
 - Scan 1: Encode DC and first few AC components, e.g., AC1, AC2
 - Scan 2: Encode a few more AC components, e.g., AC3, AC4, AC5
 - ...
 - Scan k: Encode the last few ACs, e.g., AC61, AC62, AC63.

Progressive Mode (Cont'd)

- 2. Successive approximation: Instead of gradually encoding spectral bands, all DCT coefficients are encoded simultaneously but with their most significant bits (MSBs) first
 - Scan 1: Encode the first few MSBs, e.g., Bits 7, 6, 5, 4.
 - Scan 2: Encode a few more less significant bits, e.g., Bit
 3.
 - ...
 - Scan m: Encode the least significant bit (LSB), Bit 0.

Chapter 10: Video compression

- Video consists of a group of frames
 - An obvious solution to video compression would be predictive coding based on previous frames
 - Compression proceeds by subtracting images: subtract in time order and code the residual error.
- We can do better. Usually the changes are small (high frame rate), and predictable (camera operations such as zoom and pan as well as motion of objects inside the frame)
 - Scene changes might mean that the frame is similar to its successor than predecessor

Video compression

- Video compression using Motion Compensation (MC):
 - Motion Estimation (motion vector search)
 - MC-based Prediction
 - Derivation of the prediction error, i.e., the difference.

Shifted and then delta

Macroblocks and Motion Vector

- MV search is usually limited to a small immediate neighborhood — both horizontal and vertical displacements in the range [-p, p].
- This makes a search window of size (2p + 1) x (2p + 1).

10.3 Search for Motion Vectors

- Macroblock based (rather than pixel based or object based (MPEG-4). The goal is to find vector that maps block between reference and target frame
- The difference between two macroblocks measured by their Mean Absolute Difference (MAD):

$$MAD(i, j) = \frac{1}{N^2} \sum_{k=0}^{N-1} \sum_{l=0}^{N-1} \left| C(x+k, y+l) - R(x+i+k, y+j+l) \right|$$

N — size of the macroblock,

k and l — indices for pixels in the macroblock,

i and *j* — horizontal and vertical displacements,

C(x + k, y + l) — pixels in macroblock in Target frame,

R(x+i+k, y+j+l) — pixels in macroblock in Reference frame.

The goal of the search is to find a vector (i, j) as the motion vector $\mathbf{MV} = (\mathbf{u}, \mathbf{v})$, such that MAD(i, j) is minimum:

 $(u,v) = \left[(i,j) | MAD(i,j) \text{ is minimum, } i \in [-p,p], j \in [-p,p] \right]$

Sequential Search

- **Sequential search**: sequentially search the whole $(2p + 1) \times (2p + 1) \times (2p$
 - + 1) window in the Reference frame (referred to as Full search)
 - a macroblock centered at each of the positions within the window is compared to the macroblock in the Target frame pixel by pixel and their respective MAD
 - The vector (i, j) that offers the least MAD is designated as the MV (u, v) for the macroblock in the Target frame
 - sequential search method is very costly assuming each pixel comparison requires three operations (subtraction, absolute value, addition), the cost for obtaining a motion vector for a single macroblock is O (p²N²)

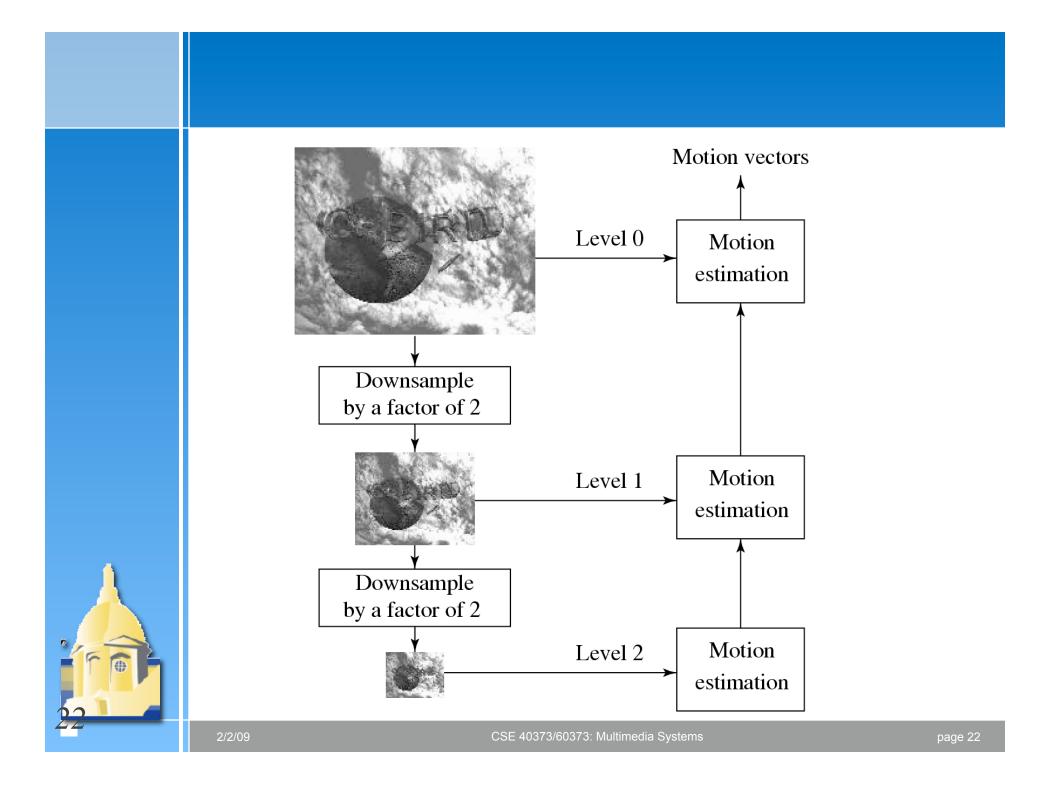

2D Logarithmic Search

- Logarithmic search: a cheaper version, that is suboptimal but still usually effective
- The procedure for 2D Logarithmic Search of motion vectors takes several iterations and is akin to a binary search:
 - initially only nine locations in the search window are used as seeds for a MAD-based search; they are marked as '1'
 - After the one that yields the minimum MAD is located, the center of the new search region is moved to it and the step-size ("offset") is reduced to half
 - In the next iteration, the nine new locations are marked as '2' and so on

Hierarchical Search

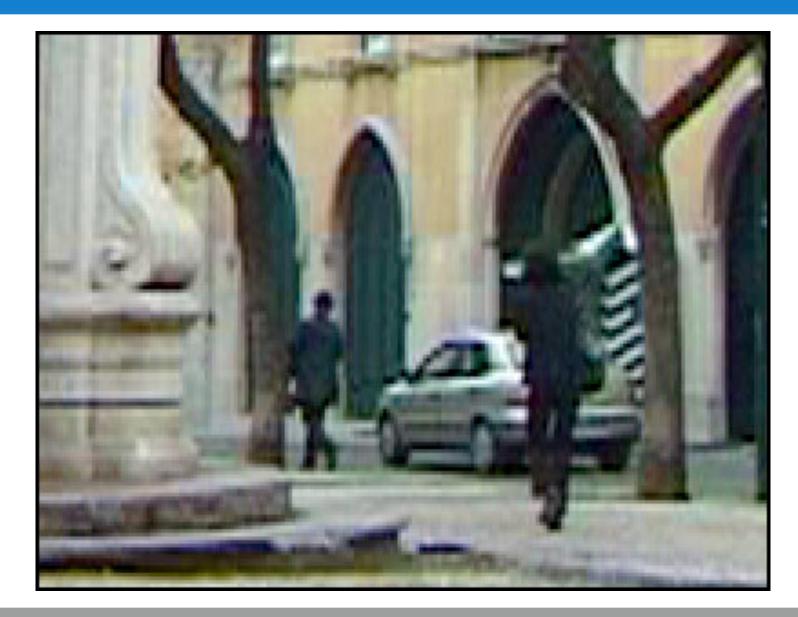

- The search can benefit from a hierarchical (multiresolution) approach in which initial estimation of the motion vector can be obtained from images with a significantly reduced resolution.
- a three-level hierarchical search in which the original image is at Level 0, images at Levels 1 and 2 are obtained by down-sampling from the previous levels by a factor of 2, and the initial search is conducted at Level 2
- Since the size of the macroblock is smaller and p can also be proportionally reduced, the number of operations required is greatly reduced

Cost of Motion Vector Search		
Search Method	earch Method OPS_per_second for 720 × 480 at 30 fps	
	p = 15	p = 7
Sequential search	29.89×10^9	$7.00 imes10^9$
2D Logarithmic search	$1.25 imes10^9$	$0.78 imes10^9$
3-level Hierarchical search	$0.51 imes 10^9$	$0.40 imes 10^9$
